

# Monophonic Fundamental Frequency Estimation

Bertrand SCHERRER

McGill University

March 8, 2007

- 1 Introduction
- 2 Spectral Location Algorithms
  - Time-Domain Periodicity Analysis
  - Cepstrum-Based Analysis
  - Harmonic Pattern Matching in the Frequency Domain
- 3 Spectral Interval Algorithms
- 4 Auditory Model Algorithms
- 5 Conclusion
  - Choice of F0 estimation technique
  - Some Exceptions to the Typology

- Historically linked to speech processing (Bell Labs)
- Very active field of research : hundreds of methods.

⇒ Will not present **ALL** the methods.

- Historically linked to speech processing (Bell Labs)
- Very active field of research : hundreds of methods.

⇒ Will not present **ALL** the methods.

- Present the **model-level typology** proposed by Anssi Klapuri in his PhD Thesis.
  - Spectral Location Algorithms
  - Spectral Interval Algorithms
  - Auditory Model Algorithms

# Autocorrelation Function

The **auto-correlation function** (ACF):

$$r(\tau) = \lim_{N \rightarrow \infty} \frac{1}{2.N + 1} \sum_{n=-N}^N x(n).x(n + \tau) \quad (1)$$

⇒ maximum when  $\tau$  corresponds to the fundamental period.

# Autocorrelation Function

The **auto-correlation function** (ACF):

$$r(\tau) = \lim_{N \rightarrow \infty} \frac{1}{2N+1} \sum_{n=-N}^N x(n) \cdot x(n+\tau) \quad (1)$$

$\Rightarrow$  maximum when  $\tau$  corresponds to the fundamental period.

# Autocorrelation Function

The **auto-correlation function** (ACF) - revisited:

$$r(\tau) = FFT(|FFT(x[n])|^2) \quad (2)$$

# Cepstrum

The **cepstrum-based** method:

$$r(\tau) = FFT(\log(|FFT(x[n])|)) \quad (3)$$

# Cepstrum

Fig.3 [Noll 67]

- A continuum of techniques in between
- Emphasize frequency partials at the harmonic locations in the spectrum

Fig.10 [Klapuri 04]

# Filter-bank Approach

In [Brown 92]:

- **Logarithmically spaced spectral components**  $\Rightarrow$  constant spacing between partials of a harmonic sound regardless of  $F_0$ .
- Fundamental estimation  $\Leftarrow$  correlating the filterbank output with spectral patterns

# Filter-bank Approach

In [Brown 92]:

- Logarithmically spaced spectral components  $\Rightarrow$  constant spacing between partials of a harmonic sound regardless of F0.
- Fundamental estimation  $\Leftarrow$  correlating the filterbank output with spectral patterns

# Filter-bank Approach

In [Brown 92]:

- Logarithmically spaced spectral components  $\Rightarrow$  constant spacing between partials of a harmonic sound regardless of F0.
- Fundamental estimation  $\Leftarrow$  correlating the filterbank output with spectral patterns

# MLE Approach

In [Doval91,93]: maximizing the likelihood of a fundamental frequency candidate given the observation of the sound partials

# Two-way Mismatch Method

Fig.1, Maher94

## Two-Way Mismatch Procedure

- **Step 1:** average of the frequency differences between each observed partial and its nearest neighbour among the predicted harmonic frequencies.

# Two-way Mismatch Method

Fig.1 Maher94

## Two-Way Mismatch Procedure

- **Step 2:** average the frequency differences between each predicted harmonic frequency and its nearest neighbour among the observed partials.

# Spectrum Autocorrelation Method

$$\tilde{r}(m) = \frac{2}{K} \sum_{k=0}^{\frac{K}{2}-m-1} |X(k)||X(k+m)| \quad (4)$$

# Basic Observation

- Any signal with more than one frequency component exhibits periodic fluctuations, beating, in its time-domain amplitude envelope.
- The fundamental period can then clearly be identified as the duration between the two highest beatings.

# Basic Observation

- Any signal with more than one frequency component exhibits periodic fluctuations, beating, in its time-domain amplitude envelope.
- The fundamental period can then clearly be identified as the duration between the two highest beatings.

Fig.12 [Klapuri04]

# Interest

Compromise between *spectral location* and *spectral interval* methods.

# Effect of Half-Wave Rectification

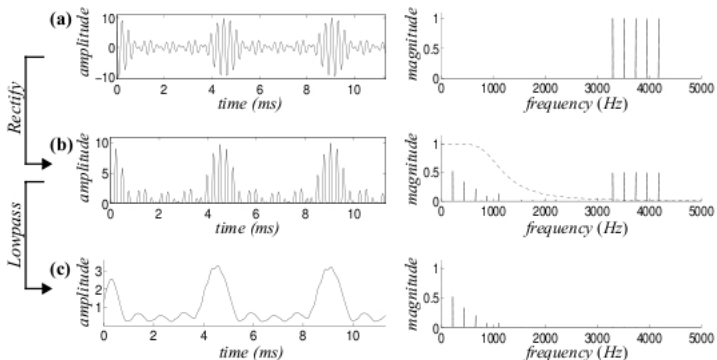

Fig.11 [Klapuri04]

# The Unitary Model

In [Meddis91]:

- ① signal is passed through a bank of bandpass filters  $\Rightarrow$  frequency selectivity of inner ear.
- ② each channel is compressed, half-wave rectified and low pass filtered  $\Rightarrow$  behaviour of the signal in the auditory nerve.
- ③ periodicity estimation in each channel using short-time ACF.
- ④ ACFs summed over all the channels, at each frame  $t$  :

$$s_t(\tau) = \sum_c r_c(\tau) \quad (5)$$

The value of the lag corresponding to the highest value of  $s_t(\tau)$  is taken to be the fundamental frequency on frame  $t$ .

# The Unitary Model

In [Meddis91]:

- ① signal is passed through a bank of bandpass filters  $\Rightarrow$  frequency selectivity of inner ear.
- ② each channel is compressed, half-wave rectified and low pass filtered  $\Rightarrow$  behaviour of the signal in the auditory nerve.
- ③ periodicity estimation in each channel using short-time ACF.
- ④ ACFs summed over all the channels, at each frame  $t$  :

$$s_t(\tau) = \sum_c r_c(\tau) \quad (5)$$

The value of the lag corresponding to the highest value of  $s_t(\tau)$  is taken to be the fundamental frequency on frame  $t$ .

- First two steps are widely accepted as general by the research community
- 3rd and 4th steps are still subject to debate and research
- Global processing chain very successful in reproducing phenomena in human hearing ⇒ still a reference today.

- First two steps are widely accepted as general by the research community
- 3rd and 4th steps are still subject to debate and research
- Global processing chain very successful in reproducing phenomena in human hearing  $\Rightarrow$  still a reference today.

- Choice of F0 estimation technique  $\Leftarrow$  prior knowledge on the signal (if any):
  - For example: Harmonicity of the signal  $\Rightarrow$  Spectral Location vs Spectral Interval

# Harmonic Signal
